# CONVEX POLYTOPES

Before defining what a convex polytope is, let us look at examples:

You can think of polytopes as geometric figures (or continuous sets of points) with linear edges, faces and higher-dimensional analogues.

## Definition

Convex polytopes are polytopes whose every two points can be connected with a line that would lie in the polytope. They can be bounded or unbounded.

# HALF-SPACES

## Definition

We can define half-space as a set of all points  $\mathbf{x}$ , such that  $\mathbf{a}^\top \mathbf{x} \leq b$ . It has a very clear geometric interpretation. In the following image, the filled space is **not** in the half space.

# HALF-SPACES

## Construction. Simple case

Consider half-space that passes through the origin, and defined by its normal vector  $\mathbf{n}$ :

It is easy to see that this half-space can be defined as "all vectors  $\mathbf{x}$ , such that  $\mathbf{n} \cdot \mathbf{x} \leq 0$ ", which is the same as using  $\mathbf{n}$  instead of  $\mathbf{a}$  in our original definition, setting  $b = 0$ .

# HALF-SPACES

## Construction. General case

In the general case there is some distance between the boundary of the half-space and the origin, let's say  $d$ .

Here the half space can be defined as "all vectors  $\mathbf{x}$ , such that  $\mathbf{x}^\top \frac{\mathbf{n}}{\|\mathbf{n}\|} \leq d$ ". This is the same as making  $\mathbf{a} = \mathbf{n}$  and  $b = d\|\mathbf{a}\|$ .

# HALF-SPACES

## Combination

We can define a region of space as an *intersection* of half-spaces  
 $\mathbf{a}_i^\top \mathbf{x} \leq b_i$ :

Resulting region will be easily described as 
$$\begin{bmatrix} \mathbf{a}_1^\top \\ \dots \\ \mathbf{a}_k^\top \end{bmatrix} \mathbf{x} \leq \begin{bmatrix} b_1 \\ \dots \\ b_k \end{bmatrix}$$

The last result allows us to write any convex polytope as a matrix inequality:

$$\mathbf{Ax} \leq \mathbf{b} \tag{1}$$

And conversely, any matrix inequality (1) represents either an empty set or a convex polytope.

## Definition

$\mathbf{Ax} \leq \mathbf{b}$  is called *H-representation* (half-space representation) of a polytope.

We can use containment in an H-polytope as a part of convex optimization problem. For example, the following QP includes such constraint:

$$\begin{array}{ll} \underset{\mathbf{x}}{\text{minimize}} & \mathbf{x}^\top \mathbf{H} \mathbf{x} + \mathbf{f}^\top \mathbf{x}, \\ \text{subject to} & \mathbf{A} \mathbf{x} \leq \mathbf{b}. \end{array} \tag{2}$$

Convex polytopes have alternative representations, such as *V-representation*. It amounts to representing polytope as a set of its vertices.

## Example

$V = \begin{bmatrix} -1 & -1 & 1 & 1 \\ -1 & 1 & 1 & -1 \end{bmatrix}$  is a V-representation of a square.

## Example

$\begin{bmatrix} 1 & 0 \\ 0 & 1 \\ -1 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \leq \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$  is an H-representation of the same square.

Given points  $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N$  their convex hull is represented as:

$$\mathcal{P} = \left\{ \mathbf{x} = \sum_{i=1}^N \alpha_i \mathbf{x}_i : \sum_{i=1}^N \alpha_i = 1, \alpha_i \in [0, 1] \right\} \quad (3)$$

See Appendix for an illustration of this formula.

We can use containment in an V-polytope as a part of convex optimization problem. For example, the following QP includes such constraint:

$$\begin{array}{ll} \underset{\mathbf{x}}{\text{minimize}} & \mathbf{x}^\top \mathbf{H} \mathbf{x} + \mathbf{f}^\top \mathbf{x}, \\ \text{subject to} & \left\{ \begin{array}{l} \mathbf{x} = \sum_{i=1}^n \alpha_i \mathbf{v}_i, \\ \sum_{i=1}^n \alpha_i = 1, \\ \alpha_i \geq 0. \end{array} \right. \end{array} \quad (4)$$

Notice that the constraint amounts to equating  $\mathbf{x}$  to a convex combination of the vertices of the V-polytope.

To transfer from H-representation to V-representation, you need to solve *vertex enumeration* problem, which is computationally expensive.

It is also possible to construct H-representation out of V-representation. Both algorithms are not convex.

# ZONOTOPES: G-REPRESENTATION

A zonotope  $\mathcal{Z}$  is a symmetric polytope defined by its *center*  $\mathbf{c}$  and *generator*  $\mathbf{G}$ :

$$\mathcal{Z} = \{\mathbf{x} : \mathbf{x} = \mathbf{G}\boldsymbol{\beta} + \mathbf{c}, \|\boldsymbol{\beta}\|_{\infty} \leq 1\} \quad (5)$$

The set  $\{\boldsymbol{\beta} : \|\boldsymbol{\beta}\|_{\infty} \leq 1\}$  is a hypercube and zonotope  $\mathcal{Z}$  is a projection (shadow) of this hypercube onto a lower-dimensional space; the projection is defined by the matrix  $\mathbf{G}$ .

Figure 1: Zonotope ([Source](#))

We can use containment in an G-polytope as a part of convex optimization problem. For example, the following QP includes such constraint:

$$\begin{array}{ll} \underset{\mathbf{x}}{\text{minimize}} & \mathbf{x}^\top \mathbf{H} \mathbf{x} + \mathbf{f}^\top \mathbf{x}, \\ \text{subject to} & \begin{cases} \mathbf{x} = \mathbf{G} \boldsymbol{\beta} + \mathbf{c}, \\ -1 \geq \beta_i \geq 1. \end{cases} \end{array} \quad (6)$$

# LINEAR APPROXIMATION OF CONVEX REGIONS

Some convex regions can be easily approximated using polytopes.

Which allows to represent constraints on  $\mathbf{x}$  to belong in such a region as a matrix inequality

Write H-representation of the following polytopes:

- Equilateral triangle
- Square
- Parallelepiped
- Trapezoid

# APPENDIX A - CONVEX HULL, 1

Let us illustrate the convex combination formula. Let  $\mathcal{P}$  be convex hull of points  $\mathbf{x}_1$ ,  $\mathbf{x}_2$  and  $\mathbf{x}_3$ :

$$\mathcal{P} = \left\{ \mathbf{x} = \sum_{i=1}^3 \alpha_i \mathbf{x}_i : \sum_{i=1}^3 \alpha_i = 1, \alpha_i \in [0, 1] \right\} \quad (7)$$

Let  $\mathbf{z}$  be a convex combination of  $\mathbf{x}_1$  and  $\mathbf{x}_3$ :  $\mathbf{z} = \beta_1 \mathbf{x}_1 + \beta_3 \mathbf{x}_3$ . Then any  $\mathbf{p} \in \mathcal{P}$  is expressed as a convex combination of  $\mathbf{z}$  and  $\mathbf{x}_2$ :  $\mathbf{p} = \gamma_1 \mathbf{z} + \gamma_2 \mathbf{x}_2$ .

## APPENDIX A - CONVEX HULL, 2

We can express  $\mathbf{p}$  as:

$$\mathbf{p} = \gamma_1 \mathbf{z} + \gamma_2 \mathbf{x}_2 = \gamma_1(\beta_1 \mathbf{x}_1 + \beta_3 \mathbf{x}_3) + \gamma_2 \mathbf{x}_2 \quad (8)$$

We can define  $\alpha_1 = \gamma_1 \beta_1$ ,  $\alpha_2 = \gamma_2$  and  $\alpha_3 = \gamma_1 \beta_3$ . Since  $\gamma_i \geq 0$  and  $\beta_i \geq 0$ , we conclude that  $\alpha_i \geq 0$ .

We can show that  $e = \alpha_1 + \alpha_2 + \alpha_3 = 1$ :

$$e = \gamma_1(\beta_1 + \beta_3) + \gamma_2 = \gamma_1 + \gamma_2 = 1 \quad (9)$$

# APPENDIX A - CONVEX HULL, 3

Previously we illustrated sufficiency of the formula's constraints. Now let us illustrate their necessity.

Dropping requirement  $\alpha_i \leq 1$ , and/or  $\alpha_i \geq 0$  and/or  $\sum_{i=1}^3 \alpha_i = 1$ , leads to inclusion of points out the convex hull, as illustrated on the figures.
